VanillaICE: Hidden Markov Models for the Assessment of Chromosomal Alterations using High-throughput SNP Arrays

Robert Scharpf and Ingo Ruczinski

February 5, 2008

1 Introduction

Chromosomal DNA is characterized by variation between individuals at the level of entire chromosomes (e.g. aneuploidy in which the chromosome copy number is altered), segmental changes (including insertions, deletions, inversions, and translocations), and changes to small genomic regions (including single nucleotide polymorphisms). A variety of alterations that occur in chromosomal DNA, many of which can be detected using high density single nucleotide polymorphism (SNP) microarrays, are linked to normal variation as well as disease and therefore of particular interest. These include changes in copy number (deletions and duplications) and genotype (e.g. the occurrence of regions of homozygosity). Hidden Markov models (HMM) are particularly useful for detecting such abnormalities, modeling the spatial dependence between neighboring SNPs. Here, we extend previous approaches that utilize HMM frameworks for inference in high throughput SNP arrays by integrating copy number, genotype calls, and the corresponding measures of uncertainty when available. Using simulated and real data, we demonstrate how confidence scores control smoothing in a probabilistic framework. The goal of this vignette is to provide a simple interface for fitting HMMs and plotting functions to help visualize the predicted states alongside the experimental data.

2 Simple Usage

2.1 Vanilla HMM

> library(VanillaICE)

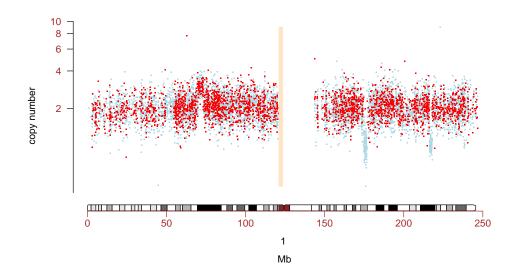

Before fitting the HMM, the data must be organized into one of the following classes for high-throughput SNP data:

- SnpCallSet (genotype calls)
- SnpCopyNumberSet (copy number estimates)
- oligoSnpSet (genotype and copy number estimates)

When pre-processing Affymetrix SNP chips with the R package oligo, an object of one of the above classes is created and can be used directly with the HMMs described in this vignette. These classes can also be created from Illumina data as described in the IlluminaHowTo vignette. The simulated data provided with this package is an instance of class oligoSnpSet

- > data(chromosome1)
- > annotation(chromosome1)

```
[1] "pd.mapping50k.hind240,pd.mapping50k.xba240"
> chromosome1
oligoSnpSet (storageMode: lockedEnvironment)
assayData: 9165 features, 1 samples
  element names: calls, callsConfidence, cnConfidence, copyNumber
experimentData: use 'experimentData(object)'
Annotation: pd.mapping50k.hind240,pd.mapping50k.xba240
phenoData
An object of class "AnnotatedDataFrame"
  sampleNames: NA06993
  varLabels and varMetadata description:
    family: trio variable
    upd: uniparental isodisomy indicator
featureData
An object of class "AnnotatedDataFrame"
  rowNames: SNP_A-1677174, SNP_A-1718890, ..., SNP_A-1677548 (9165 total)
  varLabels and varMetadata description:
    dbsnp_rs_id: dbsnp_rs_id
    chromosome: chrom
    ...: ...
    enzyme: enzyme
    (8 total)
Annotation [1] "pd.mapping50k.hind240,pd.mapping50k.xba240"
   Before deciding whether to fit a HMM, plot the data:
> gp <- new("ParSnpSet")</pre>
> gp <- getPar(gp, chromosome1)</pre>
> plotSnp(object = gp, snpset = chromosome1)
NULL
```

The HMM assumes that the copy number estimates, conditional on the hidden state, are approximately Gaussian. A log transformation is often helpful:

```
> copyNumber(chromosome1) <- log2(copyNumber(chromosome1))</pre>
```

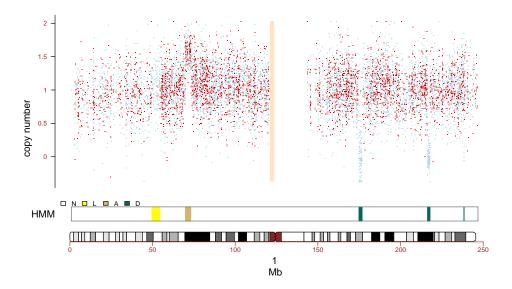

See the documentation pages in the R package *VanillaICE* for more information about the chromosome1 example dataset. Parameters for fitting the HMM are obtained by generating an instance of the class HmmParameter. By default, the HMM assumes the hidden states are deletion (D), normal (N), LOH (L), and amplification (A). See the HmmParameterClass vignette for more information. An instance of the class is created by the method new:

```
> params <- new("HmmParameter", chromosome1, states = c("D",
      "N", "L", "A"), cn.location = log2(c(1, 2, 2, 3)))
[1] "Calculating emission probabilities for genotype calls.... "
[1] "Calculating emission probabilities for copy number estimates... "
> class(params)
[1] "HmmParameter"
attr(, "package")
[1] "VanillaICE"
  We may then fit the HMM by
> fit <- hmm(params, chromosome1)</pre>
Instance of class HmmPredict

                                               NA
                                                          NA
10 NA06993
              1
                    D
                       0.098
                                5 238.320 238.418 238.30267 238.41786
11 NA06993
                    N 8.431 160 238.430 246.861 238.41786 246.86099
```

See [2] for a more complete description of the simulated dataset and the features detected by this HMM. We may plot the data along with the predictions as follows:

```
> fn <- featureNames(params)
> idx <- match(fn, featureNames(chromosome1))
> chromosome1 <- chromosome1[idx, ]
> gp <- new("ParHmmSnpSet")
> gp <- getPar(gp, snpset = chromosome1)
> plotSnp(object = gp, snpset = chromosome1, hmmPredict = fit)
```

2.2 Integrating Confidence Estimates (ICE)

In this section, we illustrate how one may fit an HMM that incorporates confidence esimates of the SNP-level summaries for genotype calls and copy number. Confidence scores (inverse of standard errors) are available for this object (see Section 2.3 for how confidence scores were derived). This information is incorporated into the HMM emission probabilities in the following way:

```
> params.ice <- new("HmmParameter", chromosome1, states = c("D",
+ "N", "L", "A"), cn.ICE = TRUE)

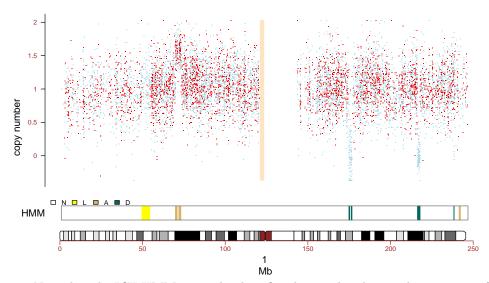

[1] "Calculating emission probabilities for genotype calls.... "
[1] "Calculating emission probabilities for copy number estimates... "

We may also incorporate the confidence scores for the genotype calls:
> params.ice <- new("HmmParameter", chromosome1, states = c("D",
+ "N", "L", "A"), cn.ICE = TRUE, gt.ICE)

[1] "Calculating emission probabilities for genotype calls.... "
[1] "Calculating emission probabilities for copy number estimates... "

We fit the HMM in the usual way
> fit.ice <- hmm(params.ice, chromosome1)
    and plot the results using the same graphical parameters as above:
> plotSnp(object = gp, snpset = chromosome1, hmmPredict = fit.ice)

[1] ""
```

Note that the ICE HMM correctly identifies the simulated normal segments in features B and C (the normal segments were simulated to have high confidence scores). Additionally, the ICE HMM detects the micro-amplification in region E (also simulated to have high confidence scores).

2.3 Confidence scores

Confidence scores for genotype calls We suggest using the CRLMM algorithm [1] for genotype calls. CRLMM (in the R package oligo) provides confidence scores ($S_{\widehat{GT}}$) of the genotype estimates (\widehat{GT}). From 269 HapMap samples assayed on the Affymetrix 50k Xba and Hind chips, we have a gold standard of the true genotype defined by the consensus of the HapMap centers. We use kernal based density estimates to obtain

$$f\left\{\right. \left.S_{\widehat{HOM}} \mid \widehat{HOM}, HOM \right. \left. \left. \right\}, \ f\left\{\right. \left.S_{\widehat{HOM}} \mid \widehat{HOM}, HET \right. \left. \right\}, \ f\left\{\right. \left.S_{\widehat{HET}} \mid \widehat{HET}, HOM \right. \right\}, \quad \text{and} \ f\left\{\right. \left.S_{\widehat{HET}} \mid \widehat{HET}, HET \right. \right\}$$

separately for the Xba and Hind 50k chips. The first term in (1), for example, denotes the density of the scores when the genotype is correctly called homozygous (HOM) and the true genotype is homozygous (HOM). See [2] for a more complete description of the methods. The data needed to estimate these densities is stored in the experiment data package callsConfidence. callsConfidence is available from the author's website.

Confidence scores for copy number estimates To illustrate how standard errors of the copy number estimate could be integrated in the HMM, the R object chromosome1 contains standard errors simulated from a shifted Gamma: Gamma(1,2) + 0.3, where 1 is the shape parameter and 2 is the rate parameter. To ascertain the effect of qualitatively high confidence scores on the ICE HMM, we scaled a robust estimate of the copy number standard deviation by $\frac{1}{2}$. Similarly, to simulate less precise $\widehat{\text{CN}}$ we scaled ϵ by 2. For more detailed information about how the data in the chromosome1 was generated, see the documentation for this object in the R package VanillaICE.

3 The HmmParameter class

The minimal information required to create an instance of class HmmParameter is

- 1. an object inheriting from the class SnpLevelSet. For instance, an oligoSnpSet.
- 2. a vector of names for the hidden states. Only the name for the normal state, "N", requires a controlled vocubulary.
- 3. optionally, one may define any of the following arguments when creating an instance of the class:
 - SCALE
 - tau.scale
 - tau
 - pi
 - beta
 - cn.location
 - cn.scale
 - cn.ICE
 - gt.ICE
 - gt.gte
 - gt.state
 - gt.confidence
 - gt.confidence.states
 - notes
 - annotation

An instance of the class is created by the method new:

```
> params <- new("HmmParameter", chromosome1, states = c("D", + "N", "L", "A"), cn.location = log2(c(1, 2, 2, 3)))
```

The object params contains all of the parameters needed for fitting the HMM, including the transition probabilities (tau), emission probabilities (beta), and initial state probabilities (pi). A summary of the parameters contained in the object params is obtained by

> params

..@ notes
```

The emission probabilities for each sample in the chromosome 1 object are stored as a vector in the params object. The emission probability matrix has dimension $S*R \times C$, where S is the number of hidden states, R is the number of rows (SNPs), and C is the number of columns (samples). To obtain the emission probabilities for the ith SNP, one may use [to subset. Currently, subset methods for the HmmParameter class are only available for 1 SNP and 1 sample at a time. For instance, the emission probabilities for the 5th SNP are:

In the future, emission probabilities may be stored in arrays to facilitate subsetting. The relevant transition probability matrices for the 5th SNP are

```
> lapply(tmp[[1]]$tau, function(x) exp(round(x, 4)))
$`SNP_A-1676440->SNP_A-1662392`
```

The probability of remaining in the same state, $P(S_t = S_{t+1})$ (the diagonal of the transition probability matrix) is a function of the distance between SNPs. The probability of transitioning to some other state is ϵ , where $\epsilon = 1 - P(S_t = S_{t+1})$. The ϵ is split among S-1 states. By default, the probability of transitioning from an altered state back to the normal state is twice as likely as the probability of transitioning between two altered states. The weights for ϵ are provided in the tau.scale matrix in the R object params

> params@tau.scale

```
D N L A
D 1.00 1.5 0.75 0.75
N 1.00 1.0 1.00 1.00
L 0.75 1.5 1.00 0.75
A 0.75 1.5 0.75 1.00
```

and can be adjusted by the SCALE argument when creating an instance of the class. For instance, here we make the probability of transitioning from an altered state to a normal state 10 times as likely as the probability of transitioning between two altered states:

```
> params <- new("HmmParameter", chromosome1, states = c("D",
+ "N", "L", "A"), cn.location = log2(c(1, 2, 2, 3)),
+ SCALE = 10)

[1] "Calculating emission probabilities for genotype calls.... "
[1] "Calculating emission probabilities for copy number estimates... "

To retrieve the copy number and genotype for the 5th SNP, one should use match:
> i <- match(names(tmp), featureNames(chromosome1))
> c(copyNumber(chromosome1[i, ]), calls(chromosome1[i, + ]))

[1] 0.5058909 1.0000000
```

4 The HmmPredict Class

The output from the HMM is an instance of the HmmPredict class and contains the predicted states as well as the breakpoints for the different states.

```
> fit
```

```
Instance of class HmmPredict

      <NA>
            <NA>
                  <NA>
                                                  NA
                            NA
                                         NA
10 NA06993
               1
                     D
                        0.098
                                 5 238.320 238.418 238.30267 238.41786
11 NA06993
                     N
                        8.431 160 238.430 246.861 238.41786 246.86099
```

The breakpoints are provided as a list, whereby each element in the list corresponds to a sample:

```
> breaks <- breakpoints(fit)
> breaks <- breaks[[1]]
> breaks <- breaks[breaks[, "state"] != "N", ]</pre>
```

One may order the altered states from biggest to smallest for each chromosome as follows:

```
> breaks <- breaks[order(breaks[, "chr"], breaks[, "size"],
+ decreasing = TRUE), ]</pre>
```

5 HMMs for different classes of data

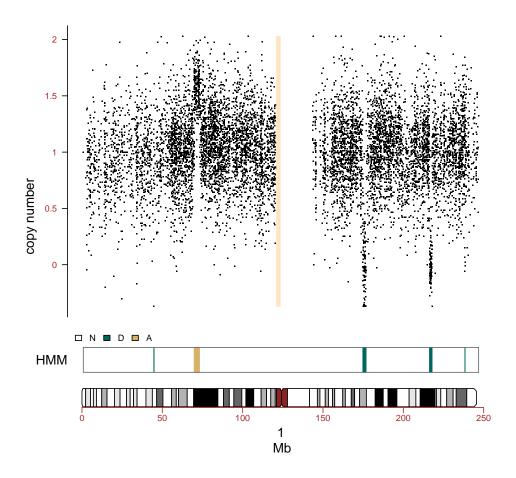

5.1 Copy number

The method hmm has a different set of underlying hidden states depending on whether copy number estimates, genotype calls, or both are available. When only copy number estimates are available, the hidden states (for autosomes) are hemizygous or homozygous deletion (one or fewer copies), normal (two copies), and amplification (three or more copies). The corresponding data class is SnpCopyNumberSet. To illustrate, we convert the chromosome1 example to an object of this class and fit the HMM.

```
> chr1.cn <- as(chromosome1, "SnpCopyNumberSet")</pre>
 params.cn <- new("HmmParameter", snpset = chr1.cn, cn.location = log2(1:3),

5.2 Genotype calls

When only genotype calls are available, the hidden states are loss and retention (ret) of heterozygosity. We define *loss* to be a sequence of homozygous SNPs longer than what we would expect to observe by chance. Note that many long stretches of homozygosity may occur as a result of a population sharing a common underlying haplotype structure; loss predictions from an HMM fit to an indvidual do not necessarily reflect the 'loss' of an allele in that individual. For illustration, we convert the chromosome1 example to an object of class HmmSnpCallSet and refit the HMM.

```
> chr1.calls <- as(chromosome1, "SnpCallSet")</pre>
> params.calls <- new("HmmParameter", snpset = chr1.calls,
      states = c("L", "N"))
[1] "Calculating emission probabilities for genotype calls.... "
> fit.calls <- hmm(params.calls, chr1.calls)</pre>

5.3 Genotype calls and copy number

Section 2 illustrates how one may fit the HMM to objects of class oligoSnpSet.

More documentation about the classes can be found in the documentation for the R package Vanil-laICE.

6 Session Information

The version number of R and packages loaded for generating the vignette were:

- R version 2.7.0 Under development (unstable) (2008-01-28 r44219), powerpc-apple-darwin8.11.0
- Locale: C
- Base packages: base, datasets, grDevices, graphics, methods, stats, tools, utils
- Other packages: Biobase 1.17.8, RColorBrewer 1.0-1, SNPchip 1.3.10, VanillaICE 1.1.6, oligo-Classes 1.1.11
